CLAIMS

[0021] What we claim as our invention is a White Space Algorithm and the embodiments of our invention for which an exclusive property or privilege is claimed are defined as follows:

1. A method for supporting the automatic creation of high quality drawings that are free from graphics and text overwrites, comprising:

a series of drawing plane bitmaps constructed by stroking graphics and text elements into equivalent pixel sets that represent committed drawing graphics and proposed drawing graphics;

the use of said bitmaps to dynamically track the ongoing state of committed drawing graphics;

the use of said bitmaps to compare proposed drawing graphics with already committed drawing graphics to determine the quality of white space available for the placement of proposed new graphics;

the use of control variables and status variables to guide adjustments along a vector, or about a rotation point, as a means of moving proposed new graphics into locations of white space.

- 2. The method according to claim 1, wherein bit level manipulations are used to track and compare committed and proposed drawing bitmaps to quantify the quality of white space available in the vicinity of tentative placement coordinates.
- The method according to claim 1, wherein the said control variables enable client applications to activate and manipulate the behavior of the white space algorithm.
- 4. The method according to claim 1, wherein the said status variables quantify the result of tracking and comparison operations and provide client applications with essential information to determine the quality of white space.

- 5. The method according to claim 1, wherein primary, secondary and supplementary slide vectors define the direction along which adjustments are made to move a proposed tentative graphics element into a location of white space.
- 6. The method according to claim 1, wherein a point at a given radius to a given coordinate and a rotation about which adjustments are made to move a proposed tentative graphics element into a location of white space.
- 7. The method according to claim 3, wherein said control variables include halos around graphics elements for controlling the proximity of proposed tentative graphics to committed graphics.
- 8. The method according to claim 1, wherein the white space algorithm operates as a server type nucleus that can be utilized by a plethora of different client applications from virtually any discipline.
- 9. The method according to claim 3, wherein said control variables allow a skip over feature to be enabled in order to suppress the drawing of a portion of a line over dense areas of committed graphics.
- 10. The method according to claim 4, wherein said status variables ensure the complete generality of the algorithm and provide information to client applications that can be applied to solve a wide class of problem.
- 11. The method according to claim 2, wherein extremely effective and highly efficient bit level manipulations are employed with a logical OR being used to add to the bit map and a Logical AND used to compare a proposed new graphic element with previously drawn graphic elements.
- 12. The method according to claim 1, wherein text elements are represented in the bitmap as a set of parallel lines and are used for the purpose of overwrite detection.
- 13. The method according to claim 1, wherein the solution is highly scalable providing performance levels that are linear and proportional to the total number of graphics elements in the completed drawing.
- 14. The method according to claim 1, wherein white space is located through the use of efficient bitmap manipulations to compare the additional graphics with

- already committed graphics to provides performance levels for comparisons that are independent of the complexity and density of the committed graphics.
- 15. The method according to claim 1, wherein the said bitmaps are also used to represent a 'must hit' filled polygon region that is used to ensure maximum overlap for the proposed graphics, achieved by inverting the objective of the bit level comparisons in favor of an overlay.
- 16. The method according to claim 12, wherein the said text elements that contain more than a single word, may be split into equivalent multi-line text elements when sufficient white space cannot be located for the initial single line text element.
